ASYMPTOTIC CLOSED-LOOP DESIGN FOR TRANSFORM DOMAIN TEMPORAL PREDICTION

TRANSFORM DOMAIN TEMPORAL PREDICTION (TDTP)

Pixel-Domain Inter Prediction is Suboptimal

- Traditional inter prediction copies pixels one-by-one.
- Suboptimal because it ignores spatial correlation.
- Transform Domain Temporal Prediction (TDTP): DCT (largely) achieves spatial decorrelation, enabling optimal one-to-one prediction.

Hidden Temporal Correlation at High Frequency

- Correlation in pixel domain is dominated by the low frequencies ($ho \approx$ 1), inspiring the traditional pixel copying prediction.
- TDTP: Accounts for variation in temporal correlation across frequency, which is hidden in pixel domain.

Sub-Pixel Motion Compensation Interferes with TDTP

- The interpolation low-pass filters scale down high-frequencies as per its magnitude response.
- Thus we apply TDTP conditioned on the sub-pixel location.

CLOSED-LOOP PREDICTOR DESIGN

• The optimal predictor for each transform domain coefficient is given by,

$$\tilde{\boldsymbol{x}}_n = \rho \hat{\boldsymbol{x}}_{n-1}$$

 Given the motion compensated reference blocks, the optimal prediction coefficient is the correlation coefficient,

$$\rho = \frac{\boldsymbol{E}(\boldsymbol{x}_n \hat{\boldsymbol{x}}_{n-1})}{\boldsymbol{E}(\hat{\boldsymbol{x}}_{n-1}^2)}$$

SHUNYAO LI, TEJASWI NANJUNDASWAMY, YUE CHEN and KENNETH ROSE SIGNAL COMPRESSION LAB, ECE DEPARTMENT, UNIVERSITY OF CALIFORNIA, SANTA BARBARA

INSTABILITY DUE TO QUANTIZATION ERROR PROPAGATION

• As we operate this predictor in closed loop, the new reconstructed frames (which are prediction reference for future frames) have different statistics, for which the correlation coefficient $\rho' \neq \rho$.

- This deviation in statistics between design and operation grows over frames.
- Thus we propose the asymptotic closed-loop (ACL) design approach for TDTP.

ASYMPTOTIC CLOSED-LOOP (ACL) DESIGN

• ACL is an iterative open-loop design technique that asymptotically optimizes the system for closed-loop operation.

- Given the reconstructed data at iteration t 1, $\hat{x}_{n-1,t-1}$ (n = 2...N), estimate the prediction coefficient for iteration t as, $\rho_t = E(x_n \hat{x}_{n-1,t-1})/E(\hat{x}_{n-1,t-1}^2)$.
- Then employ open-loop prediction to generate, $\tilde{x}_{n,t} = \rho_t \hat{x}_{n-1,t-1}$.
- Since ρ_t is directly optimized for the statistics of $\hat{x}_{n-1,t-1}$ (n = 2...N), the prediction $\tilde{x}_{n,t}$ is guaranteed to improve.
- Better prediction usually leads to better reconstruction, $\hat{x}_{n,t}$, and vice versa.
- The reconstruction error decreases over iterations and on convergence, $\hat{x}_{n,t-1} = \hat{x}_{n,t}$, which is equivalent to the closed-loop system.

TWO LOOP ASYMPTOTIC CLOSED-LOOP (ACL) DESIGN FOR TDTP

- In video coding, encoder decisions (e.g. mode decisions, motion vectors, quantization, etc.) are dependent on the prediction.
- Thus we proposed a two-loop design scheme: Inner loop: Estimate prediction coefficient ρ via ACL with encoder decisions fixed. Outer loop: Update encoder decisions with ρ fixed.
- We design different prediction coefficients conditioned on: sub-pixel location, quantization parameter (QP), skip/non-skip mode

EXPERIMENTAL RESULTS

- transform size are restricted to 8x8, and the motion search is at half-pixel precision. and 4.96% outside training set (Exp2).
- The proposed approach was implemented in HM 14.0. Both prediction size and • The average bitrate reduction over standard HEVC is 6.53% for training set (Exp1)
- In Exp2 we provide a choice of 8 sets of prediction coefficients at the encoder with an overhead of 3 bits per sequence. The difference between the two experiments suggests further scope for adaptivity.
